

# Fluid Mechanics

*or*

“Back by popular demand!”

Paul Pounds

23 April 2013

University of Queensland

---

# But first...

---

Some house keeping

# Calendar at a glance

Week	Dates	Lecture	Reviews	Demos	Assessment submissions
1	25/2 – 1/3	Introduction			
2	4/3 – 8/3	Principles of Mechatronic Systems design			
3	11/3 – 15/3	Principles of Sailing			Design brief
4	18/3 – 22/3	Sensor Fusion and Filtering	Progress review 1		
5	25/3 -29/3	Your Soldering is Terrible			
Break	1/4 – 5/4				
6	8/4 – 12/4	3D printing	Progress seminar		
7	15/4 – 19/4	Image Processing on Microcontrollers		25% demo	
8	22/4 – 26/4	Fluid mechanics			
9	29/4 – 3/5	Q&A	Progress review	50% demo	
10	6/5 – 10/5	Q&A			
11	13/5 – 17/5	Q&A		75% demo	Preliminary report
12	20/5 – 24/5	Q&A			
13	27/5 – 31/5	Closing lecture		Final testing	Final report and addendum

You are here →

Precipitous!

---

# Progress reviews next week

---

- You all know the drill now
  - 4 minutes to show 3 weeks progress
- Tutors are instructed to be merciless
  - You must present **EVIDENCE** of your work
  - We will not take your word for it
  - Pass/fail caps will be enforced
- Session sign-ups open this evening and run until Sunday night
  - Get in early if you can't make just any session!

---

# End of lecture schedule

---

- Changing to Question and Answers sessions
  - This will be the last by-request lecture topic
  - If you have particular questions about a topic, come see me one on one and we'll go through it
- Meeting at the same time, same place
  - Start with usual announcements/house-keeping
  - If numbers are low, segue to Wordsmiths ~9:10

---

# FAQ Roundup

---

- **How terrified should we be?**
  - Not too terrified. Enough time remains in the semester to do a good job.
- **How many fans will there be?**
  - Two to four fans, depending on need.

---

# Onwards

---

Fluid mechanics ho!

---

# Some meta-commentary

---

- When you say “Paul, tell me about X!”, I realise what you are really saying is: “Paul, tell me how to use X to solve my problem!”
- As usual, I will tell you about fluids, and then give you specific pointers and tools for solving the particular problem.

# Some thoughts about fluids

- Unsurprisingly, air and water are both fluids
  - Fluids are composed of many tiny particles
- Common false assumptions:
  - Fluids are incompressible
  - Fluids are inviscid
  - Fluids have negligible mass

---

# Fundamental reality stuff

---

In a closed system:

- Mass, energy, and momentum: constant
- Shape, volume, temperature: not constant

Fluid flows are directed by forces acting upon the individual particles, and (by extension) the flow as a whole

---

# Fluid statics

---

- At rest, all fluid forces balance
  - Gravity (hydrostatic) pressure, thermal expansion pressure:

( )

$P$ : pressure,  $g$ : accl. due to gravity,  $\rho$ : fluid density,  $h$ : height,  $M$ : molecular weight,  
 $k$ : Boltzman constant,  $T$ : absolute temperature

---

# Momentum

---

- Air has mass and velocity
  - Travels in constant direction until acted upon by a force
- Kinetic energy of flows can be non-trivial
  - Sails and turbines depend on this!

—

$E$ : kinetic energy,  $\rho$ : density of air,

$V$ : fluid volume,  $v$ : velocity

# Vorticity

- Fluids can rotational energy
  - Each particle is moving quasi-linearly, but the overall body of particles acts like it is rotating
  - Rotation centres are called “vorticities”
  - Range from very small to very, very large!

Vortices shed from a cylinder  
[Cesareo de La Rosa Siqueira]

Wingtip vortex [DLR]

Hurricane Sandy

# Viscosity

- Frictional forces between particles moving with different velocities
  - Dissipative effect: turns kinetic energy into heat
  - Dependent on fluid type and temperature
- Strongly influences fluid dynamics at small flow scales
  - Gives rise to vorticity

# Navier-Stokes equation

- Put all these different effects together in an energy conservation equation:

$$\left( \underbrace{\quad}_{\text{Mass rate change}} \underbrace{\quad}_{\text{Flow volumetric change}} \underbrace{\quad}_{\text{Stress tensor (pressure and viscosity)}} \underbrace{\quad}_{\text{Body forces on fluid (eg. gravity)}} \right)$$

This is an expression of Newton's second law  
(Bernoulli's principle is a special case of N-S)

---

# Laminar vs turbulent flow

---

Fluid systems give rise to chaotic behaviour

- Laminar flow

- Parallel streamlines
- Smooth pressure gradients

becomes

- Turbulent flow

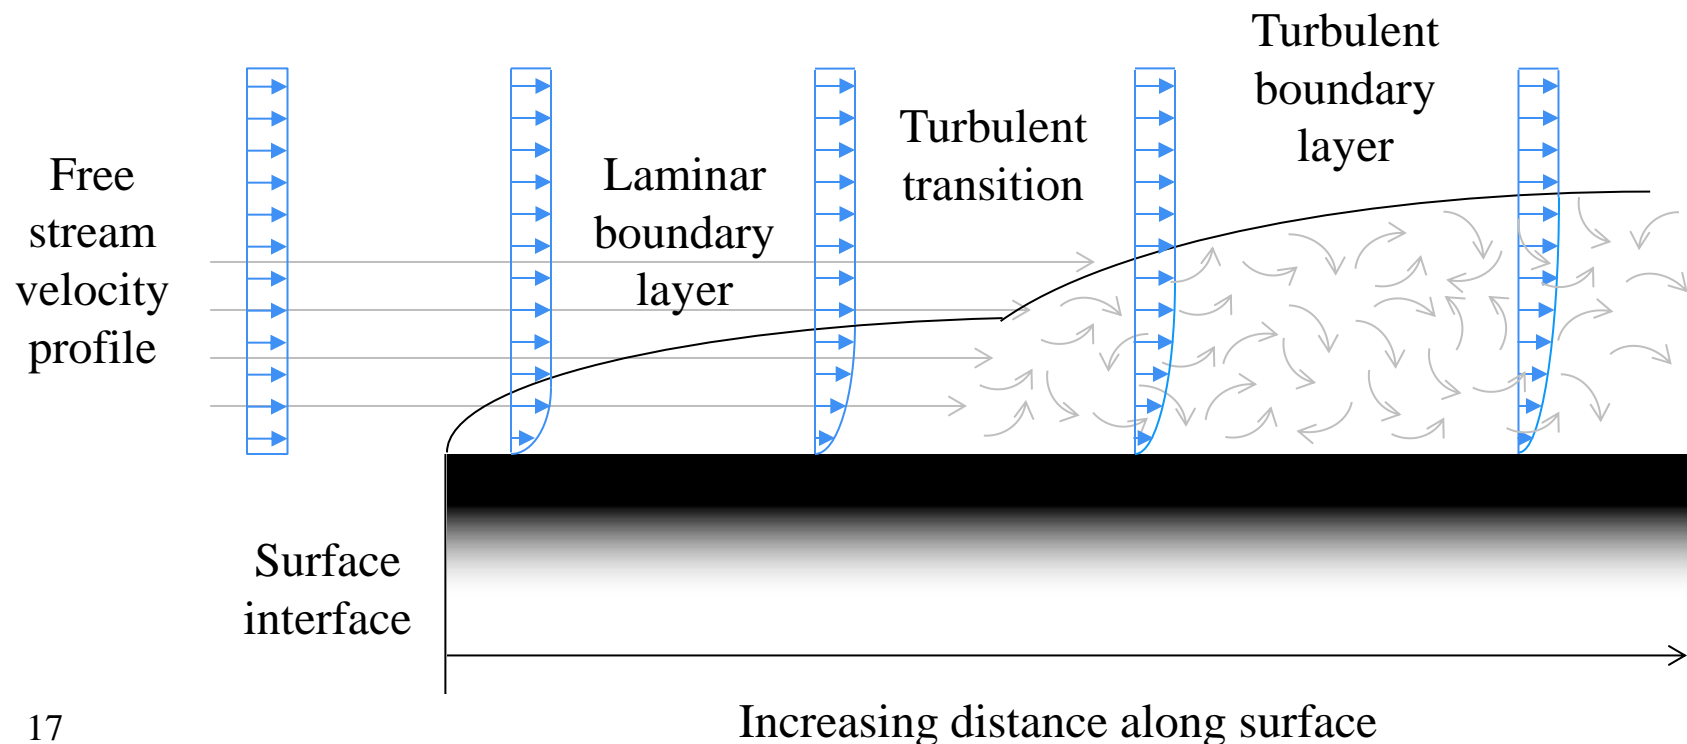

- Erratic movement of particles
- Chaotic mixing of fluid layers

# Flow development

- Laminar flow ‘develops’ into turbulent flow when interacting with surfaces

---

# Reynold's Number

---

- Measure of the development of the flow

—

$v$ : flow velocity,  $\rho$ : fluid density,  $\mu$ : fluid viscosity,  
 $L$ : “characteristic length”

- Characterises dynamic scaling of flow
  - Fluid-body interactions differ at different  $Re^*$ :
    - $Re < 10,000$  is highly viscous
    - $Re > \sim 200,000$  is dominated by flow inertia
    - $Re > \sim 1,000,000$  is turbulent

---

# Characteristic length

---

- $L$  is a parameter of the interacting surface geometry – application specific:
  - Airfoils: wing chord length
  - Flat surface: length along surface
  - Channels: channel width
  - Pipes: pipe diameter
  - Cylinders/spheres: cross-section diameter

*Why?* Because that's just how it is!\*

\*More specifically because *meaning* derived from  $Re$  is application specific

---

# Boundary conditions

---

- Consider a shape in an on-coming flow:
  - The flow adheres to the surface of the shape

Blue lines are streamlines; locally tangent to velocity field

# Boundary conditions

- Consider a shape in an on-coming flow:
  - The flow adheres to the surface of the shape

Stagnation points

Blue lines are streamlines; locally tangent to velocity field

# Boundary conditions

- Pressure increases where flow ‘bunches up’,  
Decreases where flow ‘spreads out’

Colours represent pressure field  
Red = high pressure, green = low pressure

---

# Some intuition

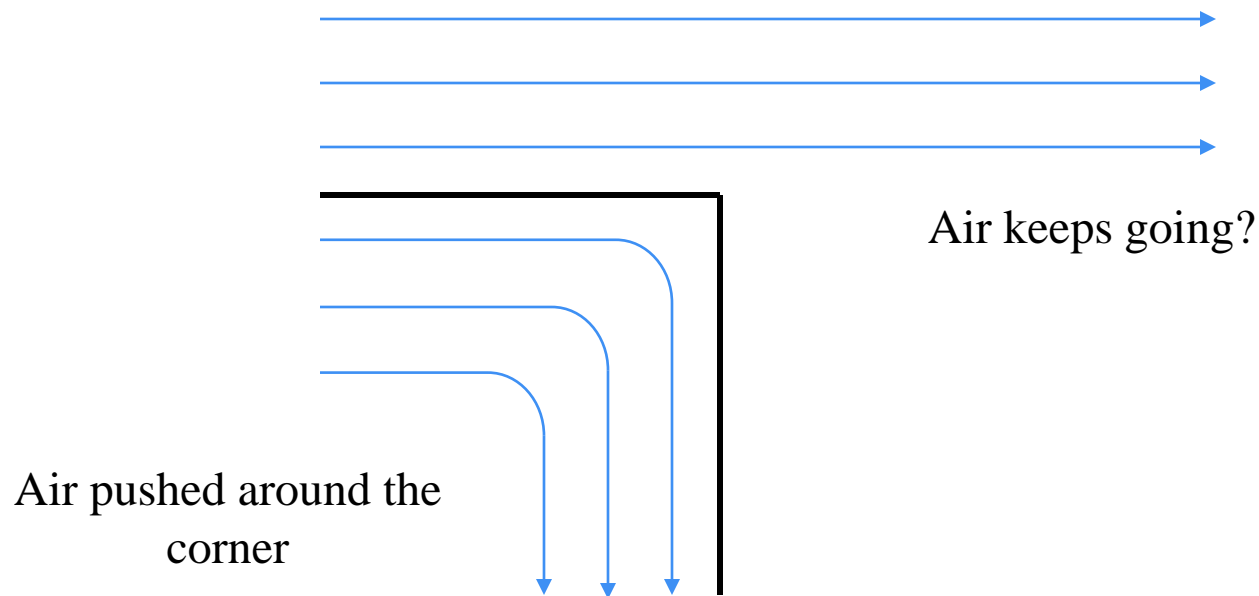

---

- Consider fluid encountering a corner

# Some intuition

- The fluid must follow the surface contour, to satisfy the boundary condition

# Some intuition

- The fluid must follow the surface contour, to satisfy the boundary condition

---

# An intuitive idea

---

- The fluid must follow the surface contour, to satisfy the boundary condition

$\therefore$  at least some fluid must  
turn the corner

# Some intuition

- Some force must act to decelerate the fluid horizontally and accelerate it vertically

# An intuitive idea

- This takes the form of increased pressure inside the corner and decreased pressure outside (suction)

---

# An intuitive idea

---

- A corresponding force acts on the corner
  - Ie. Newton's third law

---

# Slightly more complicated

---

- Now consider a symmetric body in a flow

# Slightly more complicated

- It would be reasonable to expect the flow pattern to be symmetric

This is true only in the (aphysical) inviscid flow case

# Slightly more complicated

- In reality, viscosity in the flow removes energy along the boundary layer

# Slightly more complicated

- The rear stagnation point shifts to the trailing edge (the Kutta condition)

# Slightly more complicated

- This is the basic idea behind wing lift

# Slightly more complicated

- This is the basic idea behind wing lift

Note: You may also hear reference to “airfoil circulation”, “vortex theory,” “potential flows”, and element or momentum methods. All are valid ways of describing the mechanics of wings

# Bodies in a flow

- The forces acting on a body in a flow can be calculated from geometric parameters
- Forces are decomposed into ‘lift’ and ‘drag’
  - Drag acts parallel to the flow (usually retarding)
  - Lift acts perpendicular to the flow

---

# Dynamic pressure

---

- Lift and drag forces are proportional to dynamic pressure:  
  
—
- This is also equal to:
  - The kinetic energy per unit volume of fluid
  - Pressure at the stagnation point minus the ambient hydrostatic pressure

# Lift and drag equations

- The lift and drag of a convex body in laminar flow is given by:

$$\begin{aligned} & - \\ & - \end{aligned}$$

where  $C_L$  and  $C_D$  are non-dimensionalised lift, drag and moment coefficients dependent on body geometry\*, and  $\rho$  is the density of air,  $A$  is the body area, and  $V$  is wind velocity

\*Data for airfoils can be found published online or found by experiment or CFD

# Pitching moment

- If the centre of pressure of a lifting surface is not coincident with its mechanical centre, the body may exhibit a ‘pitching moment’:

—

# Polar plots

- $c_l$  and  $c_d$  also depend on ‘angle of attack’  $\alpha$ 
  - AoA is measured from the ‘zero lifting line’, the orientation which produces no lift

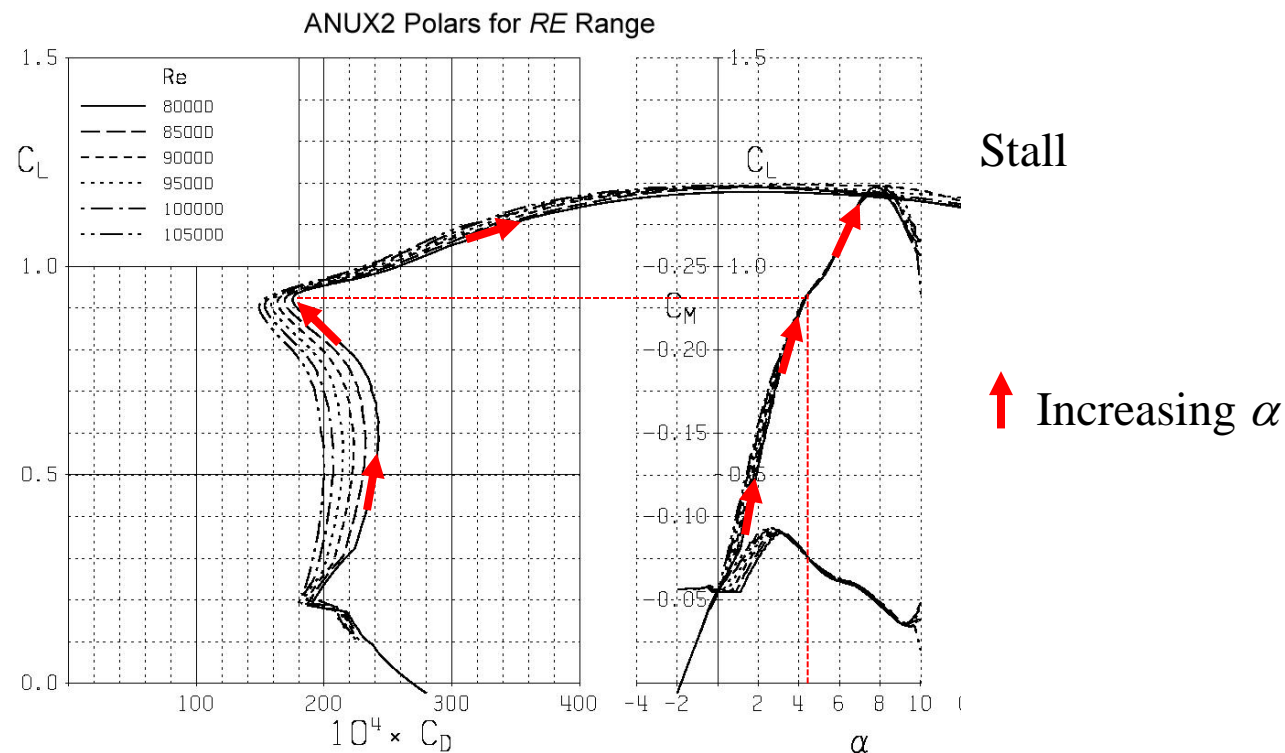

# Flow separation

- At extreme angles of attack, an airfoil's flow may separate
  - That is, the boundary layer detaches and becomes turbulent
  - This produces high drag and little lift

# Polar plots

- $c_l(\alpha)$  and  $c_d(\alpha)$  vs  $\alpha$  is nearly linear for some airfoils, but very non-linear for others
  - Plotted against each other on a ‘polar plot’

---

# Questions?

---

---

# Tune-in next time for...

---

## Questions and Answers Vol. 1

*or*

“Why didn’t you ask me that sooner!?”

Fun fact: Two people accounted for 80 per cent of lecture requests.
